The Chain Rule for Taking a Derivative

The derivative of:

$$\frac{d}{dx}(u(v(x))) = u'(v(x)) \bullet v'(x)$$

outer

inner

derivative of the outer evaluated at the inner

derivative of the inner

a FUNCTION OF A FUNCTION, a function and its argument a function, an outer function and the inner function, is the product of the derivative of the outer evaluated at the inner and the derivative of the inner.

Integration by Substitution is a procedure that at first may look too long to complete, but, with a little exposure, much of the time, may be completed mentally.

Integration by Substitution

The antiderivative of:

$$\int u'(v(x)) \bullet v'(x) dx = u(v(x)) + C$$

derivative of the outer evaluated at the inner

derivative of the inner

outer evaluated at the inner

C

the PRODUCT OF THE DERIVATIVE OF THE OUTER FUNCTION EVALUATED AT THE INNER FUNCTION AND THE DERIVATIVE OF THE INNER FUNCTION is the outer function evaluated at the inner plus a constant.

The integrand must have these as "factors"

- dx, the differential of x
- an "outer function" evaluated at an "inner function,"
- the derivative of the "inner function," and
- may be off by a constant -- need a constant or have an extra constant factor.

The strategy is to:

- rewrite the integral using a new independent variable, u, to replace the more complicated original independent variable, x,
- then complete the easier integration,
- then replace the u with the x if needed.

On this page computation is shown in two areas, the intergal equations and the computation with u.

To Take An Antiderivative By Substitution

$$\int_{\sqrt{\pi}}^{\sqrt{3\pi/2}} \sin(x^2) x \, dx =$$

$$u = x^2$$

$$du / dx = 2x$$

$$du = 2x \, dx$$

$$\frac{1}{2} du = x \, dx$$

$$\text{new } b = u(\sqrt{3\pi/2}) = (\sqrt{3\pi/2})^2 = \frac{3\pi}{2}$$

$$\text{new } a = u(\sqrt{\pi}) = (\sqrt{\pi})^2 = \pi$$

$$\frac{1}{2} \int_{\pi}^{3\pi/2} \sin(u) du =$$

$$\frac{1}{2} [-\cos(u)]_{\pi}^{3\pi/2} =$$

$$\frac{1}{2} [\cos(u)]_{3\pi/2}^{\pi} =$$

$$\frac{1}{2} [\cos(\pi) - \cos(\frac{3\pi}{2})] =$$

$$\frac{1}{2} [-1 - 0] = \frac{-1}{2}$$

1. Declare the "inside function" to be u.
2. Take the derivative of u.
3. Multiply by dx, the differential of x to isolate du, the differential of u.
4. Isolate the dx and any factors containing x on one side of the equation so it is (possible x factors)(dx).
5. If needed, multiply or divide both sides by a constant so (possible x factors)(dx) is alone -- isolated -- on one side.
6. Go back to the original integral.
7. Put u in place of the original function.
8. Remove the (possible x factors)(dx) expression, and replace it with the its equivalent expression which includes du.
9. If the problem is a definite integral, rewrite the bounds of integration in terms of u, not x.
 the new upper bound b = u(b)
 the new lower bound a = u(a)
10. Integrate the rewritten integral.
11. If the problem is an indefinite integral, rewrite the result in terms of x, and add the + C.
